TUBERCULOSIS IN THE UNITED STATES

Tuberculosis, all forms, once the leading cause of death in the United States, has dropped to sixteenth place. Since 1900, when annual mortality data were first compiled for the death-registration area, mortality from tuberculosis has decreased almost without interruption. Starting in 1946, the speed of decline of the death rate for this cause accelerated. The average annual decrease between 1939 and 1945 was about 3 percent; between 1945 and 1951 the rate dropped 10 percent per year; and between 1951 and 1953 the decrease was 22 percent per year. Since 1953, reduction in tuberculosis mortality has not been so rapid, the decline in rate from 1953 to 1954 was 17 percent and from 1954 to 1960, about 9 percent per year. The estimated tuberculosis death rate for 1960 was 5.9 per 100,000 population, as compared with 6.5 for 1959.

Provisional reports from State Health Departments indicate that approximately 55,097 new cases of active and probably active tuberculosis were reported in the continental United States during the calendar year 1960 compared to 56,951 in 1959.

†Per 100,000 population residing in United States, excluding Armed Forces overseas. ‡Provisional. §Estimated. (x)50 states and the District of Columbia (including Alaska and Hawaii). (..)=Not available. Note: Series for period 1947-1960 are data for continental United States. (Ref.f)

TUBERCULOSIS PREVALENCE IN THE UNITED STATES

The U.S. Public Health Service states that "At the beginning of 1956, there were an estimated 250,000 active cases of tuberculosis in the continental United States. Of this number, 150,000 or 60 percent, were known to State and local health departments. The rest of the estimated number comprised unknown cases, that is, currently unreported cases and a small number previously reported but since lost to supervision The estimates show that there also were 550,000 inactive cases. Of these, 250,000 were known to the health departments. The total number of active and inactive cases was estimated at 800,000 In addition, there were an estimated 1,200,000 persons who once had tuberculosis but who do not now require supervision according to State and local health department standards. Although these persons do not now require public health supervision, they constitute a reservoir of potential cases susceptible to reactivation." (Ref.g)

Estimate of Tuberculosis Prevalence in the United States
TUBERCULOSIS CASES AND PERSONS WHO ONCE HAD TUBERCULOSIS
1952 and 1956

Category	1952	1956
TOTAL CASES	950,000	800,000
Known	450,000	400,000
Unknown	500,000	400,000
Active cases	350,000	250,000
Known	200,000	150,000
Unknown	150,000	100,000
Inactive cases	600,000	550,000
Known	250,000	250,000
Unknown	350,000	300,000
Persons who once had tuberculosis ...	1,050,000	1,200,000
Total cases plus persons who once had tuberculosis	2,000,000	2,000,000

Note: All estimates rounded to the nearest 50,000. More current data not available.

According to the National Tuberculosis Association of the 178 million Americans on January 1, 1960, 36 million were infected with tuberculosis. "Most new cases will come from people now infected. The 20 percent of our nation's population estimated to have been infected with TB germs sometime in the past will contribute three out of four of the new cases in the next few years. The rest will come from people not now infected."

LARGE AMERICAN CITIES

During 1960 twenty-six American cities with thirty-one million people reported 21,242 new cases and 2,975 tuberculosis deaths. In some instances for the period 1956-1960 an increase or decrease in the tuberculosis cases was due in part to modifications of case-finding activities and therefore the case rates did not always reflect accurately changes in the incidence of tuberculosis. However, the data from this survey indicate clearly that there are still substantial numbers of persons with active tuberculosis to be found, isolated and provided with adequate medical care and treatment.

Thirteen of these urban centers recorded no change or a slight rise in their tuberculosis death rates in 1960.

The combined population of the twenty-six cities comprises seventeen percent of the United States total. Last year these cities contributed thirty-eight percent of the newly reported active cases and twenty-eight percent of the tuberculosis deaths.

New York City, with the greatest number of new cases (4,699) and deaths (810) accounted for twenty-two percent of the new cases and twenty-seven percent of the deaths in the twenty-six cities. With a population of 7,781,984, New York City comprises one-quarter of the population of the cities reported upon.

Four percent of the people in the United States are New York City residents but they were responsible for eight percent of the tuberculosis new active cases and deaths in 1960.

(See Tables on pages 90-92)
